BIERMANN INTERPOLATION OF BIRKHOFF TYPE

MARIUS BIROU

Abstract. If \( P_0, P_1, \ldots, P_r \) and \( Q_0, Q_1, \ldots, Q_r \) are Birkhoff univariate projectors which form the chains
\[ P_0 \leq P_1 \leq \cdots \leq P_r, \quad Q_0 \leq Q_1 \leq \cdots \leq Q_r, \]
we can define the Biermann operator of Birkhoff type
\[ B_r^B = P'_0 Q''_r \oplus P'_1 Q''_{r-1} \oplus \cdots \oplus P'_r Q''_0, \]
where \( P'_1, \ldots, P'_r, Q''_1, \ldots, Q''_r \) are the parametric extension.

We give the representations of Biermann interpolant of Birkhoff type for two particular cases (Abel-Goncharov and Lidstone projectors) and we calculate the approximation order of Biermann interpolant in these cases.

MSC 2000. 41A63, 41A05, 41A80.

Keywords. Biermann interpolation, Birkhoff interpolation, chains of projectors, approximation order.

1. PRELIMINARIES

Let \( X, Y \) be the linear space on \( R \) or \( C \). The linear operator \( P \) defined on space \( X \) is called projector if \( P^2 = P \). The operator \( P^c = I - P \), where \( I \) is identity operator, is called the remainder projector of \( P \). If \( P \) is projector on space \( X \) then the range space of projector \( P \) is denoted by
\[ \mathcal{R}(P) = \{ Pf \mid f \in X \}. \]
The set of interpolation points of projector \( P \) is denoted by \( \mathcal{P}(P) \).

Proposition 1. If \( P, Q \) are comutative projectors then
\[ \mathcal{R}(P \oplus Q) = \mathcal{R}(P) + \mathcal{R}(Q), \]
\[ \mathcal{P}(P \oplus Q) = \mathcal{P}(P) \cup \mathcal{P}(Q). \]

If \( P_1 \) and \( P_2 \) are projectors on space \( X \), we define relation \( \leq \) by
\[ P_1 \leq P_2 \iff P_1 P_2 = P_1. \]
Let \( f \in C(X \times Y) \) and \( x \in X \). We define \( f^x \in C(Y) \) by
\[ f^x(t) = f(x, t), \quad t \in Y. \]
For \( y \in Y \) we define \( y f \in C(X) \) by
\[ y f(s) = f(s, y), \quad s \in X. \]
Let $P$ be a linear and bounded operator on $C(X)$. The parametric extension $P'$ of $P$ is defined by
\begin{equation}
(P'f)(x, y) = (P^y f)(x).
\end{equation}
If $P$ is a linear and bounded operator on $C(Y)$ then the parametric extension $Q''$ of $Q$ is defined by
\begin{equation}
(Q''f)(x, y) = (Q^x f)(y).
\end{equation}

\textbf{Proposition 2.} Let $r \in \mathbb{N}$, $P_0, P_1, \ldots, P_r$ be univariate interpolation projectors on $C(X)$ and $Q_0, Q_1, \ldots, Q_r$ univariate interpolation projectors on $C(Y)$. Let $P'_0, \ldots, P'_r, Q''_0, \ldots, Q''_r$ be the corresponding parametric extension. We assume that
\begin{equation}
P_0 \leq P_1 \leq \cdots \leq P_r, \quad Q_0 \leq Q_1 \leq \cdots \leq Q_r.
\end{equation}
Then
\begin{equation}
B_r = P'_0 Q''_r \oplus P'_1 Q''_{r-1} \oplus \cdots \oplus P'_r Q''_0
\end{equation}
is projector and it has representation
\begin{equation}
B_r = \sum_{m=0}^{r} P'_m Q''_{r-m} - \sum_{m=0}^{r-1} P'_m Q''_{r-m-1}.
\end{equation}
Moreover, we have
\begin{equation}
B^c_r = P^c_r + P^c_{r-1} Q^c_0 + \cdots + P^c_0 Q^c_{r-1} + Q^c_r - (P^c_0 Q^c_0 + \cdots + P^c_0 Q^c_r),
\end{equation}
where $P^c = I - P$, $I$ the identity operator.

For the proof of Proposition 2 one can see [6].

\textbf{Remark 3.} If $P_i$, $i = 0, r$, and $Q_j$, $j = 0, r$, are Lagrange interpolation projectors which form the chains with respect to relation “≤”, the projector $B_r$ is called Biermann interpolation projector (see [6]). In [10] we instead the Lagrange projectors by Hermite projectors. In this article, our objective is to construct chains of Birkhoff interpolation projectors and, with their aid, the Biermann interpolant of Birkhoff type.

\section{Main Result}

Let be the univariate projectors of Birkhoff interpolation $P_0, \ldots, P_r, Q_0, \ldots, Q_r$
given by relations
\begin{equation}
(P_m f)(x) = \sum_{i=0}^{k_m} \sum_{p \in I_{i,m}} f^{(p)}(x_i) \delta_{ip}(x), \quad 0 \leq m \leq r,
\end{equation}
\begin{equation}
(Q_n g)(y) = \sum_{j=0}^{l_n} \sum_{q \in J_{j,n}} g^{(q)}(y_j) \delta_{jq}(y), \quad 0 \leq n \leq r.
\end{equation}
Assume that
\[ \{x_0, \ldots, x_k\} \subseteq [a, b], \quad \{y_0, \ldots, y_l\} \subseteq [c, d] \]
with
\[ 0 \leq k_0 \leq k_1 \leq \cdots \leq k_r, \quad 0 \leq l_0 \leq l_1 \leq \cdots \leq l_r \]
and
\[ I_{i,m} \subseteq I_{i,m+1}, \quad i = 0, k_m, \quad m = 0, r - 1, \]
\[ J_{j,n} \subseteq J_{j,n+1}, \quad j = 0, l_n, \quad n = 0, r - 1. \]

The cardinal functions \( b^m\nu_{jp}, m = 0, r, \) and \( \tilde{b}^n\nu_{jq}, n = 0, r, \) satisfy
\[ \begin{aligned}
  b^m\nu_{jp}(x) &= 0, & \nu \neq i, & j \in I_{\nu,m} \\
  b^m\nu_{jp}(x_i) &= \delta_{jp}, & j \in I_{i,m} \\
\end{aligned} \]
for \( p \in I_{i,m}, \nu, i = 0, k_m \) and, respectively,
\[ \begin{aligned}
  \tilde{b}^n\nu_{jq}(y) &= 0, & \nu \neq j, & i \in J_{\nu,n} \\
  \tilde{b}^n\nu_{jq}(y_j) &= \delta_{iq}, & i \in J_{j,n} \\
\end{aligned} \]
for \( q \in J_{j,n}, \nu, j = 0, l_n. \)

**Theorem 4.** The parametric extensions
\[ P'_0, \ldots, P'_r, \quad Q''_0, \ldots, Q''_r \]
are bivariate interpolation projectors which form the chains
\[ P'_0 \leq \cdots \leq P'_r, \quad Q''_0 \leq \cdots \leq Q''_r. \]

**Proof.** Let be \( 0 \leq m_1 \leq m_2 \leq r. \) Then
\[ k_{m_1} \leq k_{m_2}, \]
\[ I_{i,m_1} \subseteq I_{i,m_2}, \quad i \leq k_{m_1}, \]

We have that
\[ \begin{aligned}
  (P'_{m_1} P'_{m_2} f)(x, y) &= \sum_{i_1=0}^{k_{m_1}} \sum_{p_1 \in I_{i_1,m_1}} \left( \sum_{i_2=0}^{k_{m_2}} \sum_{p_2 \in I_{i_2,m_2}} f^{(p_2,0)}(x_{i_2}, y) b^m_{i_2 p_2}(x_{i_2}) \right) b^m_{i_1 p_1}(x). \\
\end{aligned} \]

But
\[ b^m_{i_2 p_2}(x_{i_1}) = \delta_{i_1 i_2} \delta_{p_1 p_2}. \]

From (12), (13) and (14) we have
\[ \begin{aligned}
  (P'_{m_1} P'_{m_2} f)(x, y) &= \sum_{i_1=0}^{k_{m_1}} \sum_{p_1 \in I_{i_1,m_1}} f^{(p_1,0)}(x_{i_1}, y) b^m_{i_1 p_1}(x) = (P'_{m_1} f)(x, y), \\
\end{aligned} \]
40 Marius Birou 4

i.e.,

\[ P'_{m_1} \leq P'_{m_2}. \]

Thus \( P'_0, P'_1, ..., P'_r \) form a chain. Analogous \( Q''_0, Q''_1, ..., Q''_r \) are projectors which form a chain.

Moreover, we have

\[ P'_m Q''_n = Q''_n P'_m, \quad 0 \leq m, n \leq r. \]

The tensor product projector \( P'_m Q''_n \) of bivariate interpolation has representation

\[
(P'_m Q''_n f)(x, y) = \sum_{i=0}^{k_m} \sum_{p \in I_i, m} \sum_{j=0}^{l_m} \sum_{q \in J_j, n} f^{(p,q)}(x_i, y_j) \tilde{h}_{ip}(x) \tilde{h}_{jq}(y)
\]

and it has the interpolation properties

\[
(P'_m Q''_n f)^{(p,q)}(x_i, y_j) = f^{(p,q)}(x_i, y_j), \quad 0 \leq i \leq k_m, \quad 0 \leq j \leq l_n, \\
p \in I_i, m, \quad q \in J_j, n.
\]

The projectors \( P'_0, ..., P'_r, Q''_0, ..., Q''_r \) generate a distributive lattice \( \xi \) of projectors on \( C([a,b] \times [c,d]) \). A special element in this lattice is

\[ B_r^{B} = P'_0 Q''_r \oplus P'_1 Q''_{r-1} \oplus \cdots \oplus P'_r Q''_0, \quad r \in \mathbb{N}, \]

called Biermann projector of Birkhoff type and which has the interpolation properties

\[
(B_r^{B} f)^{(p,q)}(x_i, y_j) = f^{(p,q)}(x_i, y_j), \quad 0 \leq i \leq k_m, \quad 0 \leq j \leq l_r-m, \quad 0 \leq m \leq r, \\
p \in I_i, m \setminus I_i, m-1, q \in J_j, r-m
\]

with \( I_i, s = \emptyset, k_s < i \leq k_{s+1}, s = -1, r-1 \) with \( k_{-1} = -1 \).

Let \( \alpha_i = |I_0, i| + \cdots + |I_{k_i}, i|, \ \beta_i = |J_0, i| + \cdots + |J_{l_i}, i|, 0 \leq i \leq r. \) The range space of projector \( B_r^{B} \) is

\[
\mathcal{R}(B_r^{B}) = \Pi_{0 \alpha_i-1} \otimes \Pi_{\beta_i-1} + \cdots + \Pi_{0 \alpha_i-1} \otimes \Pi_{\beta_0-1}.
\]

The properties \([15]\) and \([16]\) result using Proposition \([1]\)

Let be \( h = b - a = d - c \) and \( q = \min \{ \alpha_r - m + 1, \beta_m, -1 \leq m \leq r \} \) with \( \alpha_{-1} = 0, \beta_{-1} = 0. \) From \([8]\) we have

\[
f(x, y) - (B_r^{B} f)(x, y) = O(h^q), \quad h \to 0.
\]
3. PARTICULAR CASES

3.1. Biermann interpolation of Abel-Goncharov type. Let be the univariate Abel-Goncharov interpolation projectors

\[(P_m f)(x) = \sum_{i=0}^{m} g_{i,m}(x) f^{(i)}(x_i), \quad m = 0, r,\]

\[(Q_n f)(y) = \sum_{j=0}^{n} \tilde{g}_{j,n}(y) f^{(j)}(y_j), \quad n = 0, r,\]

i.e.,

\[k_m = m, \quad m = 0, r,\]

\[l_n = n, \quad n = 0, r,\]

\[I_{j,i} = \{j\}, \quad j = 0, r, i = j, r,\]

\[J_{i,j} = \{i\}, \quad i = 0, r, j = i, r.\]

According to [5], the cardinal functions \(g_{i,m}, i = 0, m,\) are given by recurrence relations

\[g_{0,m}(x) = 1,\]
\[g_{1,m}(x) = 1 - x_0,\]
\[g_{i,m}(x) = \frac{1}{i!} \left( x^i - \sum_{j=0}^{i-1} g_{i,m}(x) \binom{i}{j} x_j^{i-j} \right), \quad i = 2, m,\]

for \(m = 0, r.\)

One remark that the cardinal functions \(g_{i,m}\) depend only the nodes \(x_0, x_1, \ldots, x_{i-1}.\) It follows that the functions \(g_{i,m}, i = 0, r,\) are the same for \(m = i, r.\)

One denotes

\[g_i(x) := g_{i,m}(x), \quad i = 0, r, \quad m = i, r.\]

We have analogous relations for the cardinal functions \(\tilde{g}_{j,n}\) and we denote

\[\tilde{g}_j(x) := \tilde{g}_{j,m}(x), \quad j = 0, r, \quad m = j, r.\]

The indices sets of derivatives satisfy the chains of equalities

\[I_{j,j} = I_{j,j+1} = \ldots = I_{j,r}, \quad j = 0, r,\]
\[J_{i,i} = J_{i,i+1} = \ldots = J_{i,r}, \quad i = 0, r.\]

It follows that relations \([11]\) hold.

We can define the Biermann operator of Abel-Goncharov type

\[(18) \quad B_{r}^{AG} = P'_{0}Q''_{r} \oplus P'_{1}Q''_{r-1} \oplus \ldots \oplus P'_{i}Q''_{0},\]

where \(P'_i, \ i = 0, r,\) and \(Q''_{j}, \ j = 0, r,\) are the parametric extensions.
Taking into account (7) we obtain the following representation for Biermann interpolant $B^A_G$

\[(B^A_G f)(x, y) = \sum_{m=0}^{r} (P_m(Q''_{r-m} - Q''_{r-m-1}) f(x, y)) = \sum_{m=0}^{r} \sum_{i=0}^{m} g_i(x)\tilde{g}_{r-m}(y) f(i,r-m)(x_i, y_{r-m}),\]

where $Q''_{r-1} = 0$.

Using Proposition 1, the Biermann interpolant $B^A_G$ has the interpolation properties

\[(B^A_G f)(i,r-j)(x_i, y_{r-j}) = f(i,r-j)(x_i, y_{r-j}), \quad i = 0, r, j = 0, i.\]

**Remark 5.** The set of nodes form a triangular grid

\[(x_0, y_r), (x_0, y_{r-1}), (x_1, y_{r-1}), \ldots, (x_0, y_1), (x_1, y_1), \ldots, (x_{r-1}, y_1), (x_0, y_0), (x_1, y_0), \ldots, (x_{r-1}, y_0), (x_r, y_0).\]

Let $h = b - a = d - c$. According to

\[
\|f(x) - P_m f(x)\| = O(h^{m+1}), \quad \text{if } f \in C^{m+1}[a, b],
\]

\[
\|f(y) - Q_n f(x)\| = O(h^{n+1}), \quad \text{if } f \in C^{n+1}[c, d],
\]

and relation (8), the approximation order of Biermann interpolant of Abel-Goncharov type is $r + 1$, i.e.,

\[(21) \quad \|f(x, y) - B^A_G f(x, y)\| = O(h^{r+1}), \quad \text{if } f \in C^{r+1}([a, b] \times [c, d]).\]

**Remark 6.** The approximation order of Biermann operator $B^A_G$ is the same with the approximation order of tensor product operator $P'_r Q''_r$. If $P$ is an interpolation projector we denote by $I_P(f)$ the set of data about $f$ (values of function $f$ and/or certain of its partial derivatives at nodes). We have

\[
|I_{B^A_G}(f)| = \frac{(r+1)(r+2)}{2},
\]

\[
|I_{P'_r Q''_r}(f)| = (r + 1)^2,
\]

and

\[I_{B^A_G}(f) \subset I_{P'_r Q''_r}(f).\]

It follows that the Biermann operator $B^A_G$ is more efficient than tensor product operator $P'_r Q''_r$. □
3.2. Biermann interpolation of Lidstone type. Let be the univariate Lidstone interpolation projectors

\[(P_m f)(x) = \sum_{i=0}^{m} [l_{0,i}^m(x) f^{(2i)}(x_0) + l_{1,i}^m(x) f^{(2i)}(x_1)], \quad m = 0, r,\]

\[(Q_n g)(y) = \sum_{j=0}^{n} [\tilde{l}_{0,j}^n(y) f^{(2j)}(y_0) + \tilde{l}_{1,j}^n(y) f^{(2j)}(y_1)], \quad n = 0, r,\]

i.e.,

\[k_0 = k_1 = \ldots = k_r = 1,\]
\[l_0 = l_1 = \ldots = l_r = 1,\]
\[I_{0,i} = I_{1,i} = \{0, 2, \ldots, 2i\}, \quad i = 0, r,\]
\[J_{0,j} = J_{1,j} = \{0, 2, \ldots, 2j\}, \quad j = 0, r,\]

If we denote \(h = x_1 - x_0 = y_1 - y_0,\) from [1] we can obtain cardinal functions by relations

\[l_{0,i}^m(x) = \Delta_i(\frac{x-x_1}{h})h^{2i},\]
\[l_{1,i}^m(x) = \Delta_i(\frac{x-x_0}{h})h^{2i},\]

\[m = 0, r, \quad i = 0, m,\]

where the functions \(\Delta_i, \quad i = 0, r,\) are given by recurrence relations

\[\Delta_0(x) = x,\]
\[\Delta_n(x) = \int_0^1 g_n(x, s) ds, \quad n \geq 1,\]

with

\[g_1(x, s) = \left\{ \begin{array}{ll}
(x-1)s, & s \leq x, \\
(s-1)x, & x \leq s,
\end{array} \right.\]
\[g_n(x, s) = \int_0^1 g_1(x, t) g_{n-1}(t, s) dt, \quad n \geq 2.\]

One remark that the cardinal function \(l_{0,i}^m\) and \(l_{1,i}^m\) don’t depend of \(m.\) We can make notation

\[l_{0,i}(x) := l_{0,i}^m(x), \quad i = 0, r, \quad m = i, r,\]
\[l_{1,i}(x) := l_{1,i}^m(x), \quad i = 0, r, \quad m = i, r.\]

We have analogous relations for cardinal functions \(\tilde{l}_{0,j}^n, \tilde{l}_{1,j}^n\) and we denote

\[\tilde{l}_{0,j}(y) := \tilde{l}_{0,j}^n(y), \quad j = 0, r, \quad n = j, r,\]
\[\tilde{l}_{1,j}(y) := \tilde{l}_{1,j}^n(y), \quad j = 0, r, \quad n = j, r.\]
The indices sets of derivatives verify relations (11) because
\[ I_{j,i} = \{0, 2, \ldots, 2i\} \subset \{0, 2, \ldots, 2i, 2i + 2\} = I_{j,i+1}, \quad j = 0, 1, \quad i = 0, r - 1, \]
\[ J_{i,j} = \{0, 2, \ldots, 2j\} \subset \{0, 2, \ldots, 2j, 2j + 2\} = I_{i,j+1}, \quad i = 0, 1, \quad j = 0, r - 1. \]

We can define the Biermann operator of Lidstone type
\[ B_r^L = P_r^0 Q_r^r \oplus P_r^1 Q_r'^r \oplus \cdots \oplus P_r^r Q_r''^r, \]
where \( P_i^l \), \( i = 0, r \), and \( Q_j^j \), \( j = 0, r \), are the parametric extensions.

From (7), we obtain the following representation for Biermann operator \( B_r^L \)
\[ (B_r^L f)(x, y) = \]
\[ = \sum_{m=0}^{r} (P_m^r (Q_r^r - m - Q_r'^r - m - 1) f)(x, y) \]
\[ = \sum_{m=0}^{r} \sum_{i=0}^{m} l_0,i(x) [\tilde{t}_{0,2r-2m}(y) f^{2i,2r-2m}(x_0, y_0) + \tilde{t}_{1,2r-2m}(y) f^{2i,2r-2m}(x_0, y_1)] \]
\[ + \sum_{m=0}^{r} \sum_{i=0}^{m} l_1,i(x) [\tilde{t}_{0,2r-2m}(y) f^{2i,2r-2m}(x_1, y_0) + \tilde{t}_{1,2r-2m}(y) f^{2i,2r-2m}(x_1, y_1)], \]
where \( Q_r''^r = 0 \).

Using Proposition 1, it follows that the Biermann projector \( B_r^L \) has the interpolations properties
\[ (B_r^L f)^{2i,2(r-j)}(x_k, y_l) = f^{2i,2(r-j)}(x_k, y_l), \quad i = 0, r, \quad j = 0, r, \quad k, l \in \{0, 1\}. \]

From (11) we have
\[ \| f(x) - P_m f(x) \| = O(h^{2m}), \quad \text{if} \ f \in C^{2m}[a, b], \]
\[ \| g(y) - Q_n g(y) \| = O(h^{2n}), \quad \text{if} \ g \in C^{2n}[c, d]. \]

Taking into account (8), the approximation order of Biermann operator \( B_r^L \) is 2r, i.e.
\[ \| f(x, y) - B_r^L f(x, y) \| = O(h^{2r}), \quad \text{if} \ f \in C^{2r}([a, b] \times [c, d]). \]

**Remark 7.** The approximation order of Biermann operator \( B_r^L \) is the same with the approximation order of tensor product operator \( P_r^r Q_r''^r \). We have
\[ |I_{B_r^L}(f)| = 2(r + 1)(r + 2), \]
\[ |I_{P_r^r Q_r''^r}(f)| = 4(r + 1)^2 \]
and
\[ I_{B_r^L}(f) \subset I_{P_r^r Q_r''^r}(f). \]
where $I_P(f)$ is the set of data about $f$ used by interpolation projector $P$. It follows that the Biermann operator $B_r^B$ is more efficient than tensor product operator $P_r^B Q_r^B$. □
